## Dynamic Programming

Fernando Lobo

1 / 49

## Dynamic Programming

- ▶ Another algorithm design technique, like Divide and Conquer, and Greedy algorithms.
- ▶ The name *Dynamic Programming* is a bit misleading.
  - ▶ *Programming*  $\Rightarrow$  suggests computer programming.
  - ▶ *Dynamic*  $\Rightarrow$  suggests something that changes through time.
- ▶ The Dynamic Programming technique has not much to do with these things!

2 / 49

## What is Dynamic Programming?

- ▶ It's a technique for solving problems.
- ▶ The idea is to solve subproblems and store their results.
- ▶ Those results are used for solving larger subproblems, and again we store their results.
- ▶ And so on until we are able to solve the complete problem.

3 / 49

## Comparison with Divide and Conquer

### Similarities

- ▶ To solve a problem we combine solutions of subproblems.

### Differences

- ▶ D&C is efficient when the subproblems are distinct.
- ▶ If we have to solve the same subproblem over and over, D&C becomes inefficient.
- ▶ With Dynamic Programming, each subproblem is only solved once.

4 / 49

## A very simple example

- A simple example: Compute the  $n^{\text{th}}$  element from the Fibonacci sequence.

$$F_n = \begin{cases} 0 & , \text{ se } n = 0 \\ 1 & , \text{ se } n = 1 \\ F_{n-1} + F_{n-2} & , \text{ se } n > 1 \end{cases}$$

5 / 49

## Pseudocode

```
FIB-REC( $n$ )  
  if  $n == 0$   
    return 0  
  if  $n == 1$   
    return 1  
  return FIB-REC( $n - 1$ ) + FIB-REC( $n - 2$ )
```

This algorithm is very bad. Why?

6 / 49

## Let's see what happens with $n = 5$

7 / 49

## Fibonacci: D&C Algorithm

- We are computing the same thing several times!
- We can prove that  $F_{n+1}/F_n \approx \frac{1+\sqrt{5}}{2} \approx 1.62$   
 $\implies F_n > 1.6^n$
- What's the running time of the algorithm?
  - $F_n$  is the sum of all the leaves of the tree.
  - $F_n > 1.6^n \implies$  tree has at least  $1.6^n$  leaves.
- Algorithm's running time is  $\Omega(1.6^n)$ .
- Implement it and try running with increasing values of  $n$ .

8 / 49

## Fibonacci: D&C Algorithm

- ▶ With  $n = 5$  we compute:
  - ▶  $F_4 \rightarrow 1$  time
  - ▶  $F_3 \rightarrow 2$  times
  - ▶  $F_2 \rightarrow 3$  times
  - ▶  $F_1 \rightarrow 5$  times
  - ▶  $F_0 \rightarrow 3$  times
- ▶ A lot of unnecessary work. Each  $F_i$  should be computed once.
- ▶ We can do it with Dynamic Programming.

9 / 49

## Fibonacci: Dynamic Programming algorithm

- ▶ The idea is to solve the problem bottom-up, starting with the base cases and storing the results in order to solve larger subproblems.

FIB-PD( $n$ )

$F[0] = 0$

$F[1] = 1$

**for**  $i = 2$  **to**  $n$

$F[i] = F[i - 1] + F[i - 2]$

**return**  $F[n]$

- ▶ Time complexity:  $\Theta(n)$ .
- ▶ Space complexity:  $\Theta(n)$ .

10 / 49

## Fibonacci: Dynamic Programming algorithm

- ▶ Space complexity can be reduced from  $\Theta(n)$  to  $\Theta(1)$  because to compute  $F_i$  we only need to keep the solutions of two subproblems:  $F_{i-1}$  and  $F_{i-2}$ .

FIB-PD-v2( $n$ )

**if**  $n == 0$

**return** 0

**if**  $n == 1$

**return** 1

$back2 = 0$

$back1 = 1$

**for**  $i = 2$  **to**  $n$

$next = back1 + back2$

$back2 = back1$

$back1 = next$

**return**  $next$

11 / 49

## Another example: Rod cutting

- ▶ Problem: Given a rod of length  $n$  and a table of prices  $p_i$  for for pieces of length  $i$  ( $i = 1, 2, \dots, n$ ), determine the maximum revenue  $r_n$  that can be obtained by cutting the rod into pieces and selling them. Assume cuts are free and rod lengths are integers.

- ▶ Example:  $n = 4$

| length $i$  | 1 | 2 | 3 | 4 |
|-------------|---|---|---|---|
| price $p_i$ | 1 | 5 | 8 | 9 |

12 / 49

## 8 ways of cutting it

13 / 49

- ▶ Best solution: cut into two pieces of size 2. Total revenue is  $5 + 5 = 10$ .
- ▶ For each  $i = 1 \dots n - 1$ , either cut or not cut  $\implies 2^{n-1}$  ways of cutting the rod.

14 / 49

## Exploiting problem structure

- ▶ Let's try to define the optimal solution in terms of optimal solutions of subproblems.
- ▶ Let  $r_i$  be the maximum revenue for a rod of length  $i$ .
- ▶ Then  $r_n$  will be the maximum of:
  - ▶  $p_n$
  - ▶  $r_1 + r_{n-1}$
  - ▶  $r_2 + r_{n-2}$
  - ▶  $\dots$
  - ▶  $r_{n-1} + r_1$

15 / 49

## Simpler decomposition

- ▶ Every optimal solution must have a leftmost piece (potentially of size  $n$  in case there's no cuts).
- ▶ Total revenue will be the cost of that piece plus the cost of the best revenue obtainable but cutting the remaining piece.
- ▶  $r_n$  is the maximum of:
  - ▶  $p_1 + r_{n-1}$
  - ▶  $p_2 + r_{n-2}$
  - ▶  $\dots$
  - ▶  $p_n + r_0$

16 / 49

## Pseudocode

```
CUT-ROD( $p, n$ )  
  if  $n == 0$   
    return 0  
   $q = -\infty$   
  for  $i = 1$  to  $n$   
     $q = \max(q, p[i] + \text{CUT-ROD}(p, n - i))$   
  return  $q$ 
```

- Very inefficient, just like the Fibonacci example.

17 / 49

## Recursion tree of CUT-ROD with $n = 4$

- Computes the same subproblems over and over.
- Running time:  $\Theta(2^n)$ .

18 / 49

## Dynamic programming approach

- Solve each subproblem once and store the result for further use.
- Do a bottom-up approach: solve smaller subproblems first.
- When we need to solve a larger subproblem, we use the pre-computed results of smaller subproblems.

19 / 49

## Dynamic programming algorithm

```
BOTTOM-UP-CUT-ROD( $p, n$ )  
  Let  $r[0..n]$  be a new array  
   $r[0] = 0$   
  for  $j = 1$  to  $n$   
     $q = -\infty$   
    for  $i = 1$  to  $j$   
       $q = \max(q, p[i] + r[j - i])$   
     $r[j] = q$   
  return  $r[n]$ 
```

20 / 49

|    | 0 | 1 | 2 | 3 | 4  |
|----|---|---|---|---|----|
| r: | 0 | 1 | 5 | 8 | 10 |

$$\begin{aligned} \max(p_1 + r_0) &= 1 \\ \max(p_1 + r_1, p_2 + r_0) &= \max(1+1, 5+0) = 5 \\ \max(p_1 + r_2, p_2 + r_1, p_3 + r_0) &= \max(1+5, 5+1, 8+0) = 8 \\ \max(p_1 + r_3, p_2 + r_2, p_3 + r_1, p_4 + r_0) &= \max(1+8, 5+5, 8+1, 10+0) = 10 \end{aligned}$$

21 / 49

## Running time

- ▶ Two nested for loops depending on  $n$ , and constant time in each iteration. Running time is  $\Theta(n^2)$ .
- ▶ We reduced from exponential to polynomial time.

22 / 49

## Reconstructing the solution

- ▶ Algorithm returned the value of the optimal solution, not the solution itself (where to cut).
- ▶ Can obtain the solution with a little modification:  $s[i]$  saves the first cut point for a rod of length  $i$ .

### EXTENDED-BOTTOM-UP-CUT-ROD( $p, n$ )

Let  $r[0..n]$  and  $s[0..n]$  be new arrays

$r[0] = 0$

**for**  $j = 1$  **to**  $n$

$q = -\infty$

**for**  $i = 1$  **to**  $j$

$q = \max(q, p[i] + r[j-i])$

$s[j] = i$

$r[j] = q$

**return**  $r$  and  $s$

23 / 49

## Reconstructing the solution

| $i$    | 0 | 1 | 2 | 3 | 4  |
|--------|---|---|---|---|----|
| $r[i]$ | 0 | 1 | 5 | 8 | 10 |
| $s[i]$ | 0 | 1 | 2 | 3 | 2  |

### PRINT-CUT-ROD-SOLUTION( $p, n$ )

$(r, s) = \text{EXTENDED-BOTTOM-UP-CUT-ROD}(p, n)$

**while**  $n > 0$

    print  $s[n]$

$n = n - s[n]$

24 / 49

## Memoization

- ▶ A technique similar to Dynamic Programming.
- ▶ Keeps the algorithm in a recursive (*top-down*) form.
- ▶ The idea is to flag unsolved subproblems with “Unknown”.
- ▶ Then, to solve a subproblem we first verify if it has already been solved.
  - ▶ If yes, we simply return the solution previously stored.
  - ▶ If not, we solve the subproblem and store its solution for further use.
- ▶ Each subproblem is only solved once.

25 / 49

## Memoized version of Cut-Rod

MEMOIZED-CUT-ROD( $p, n$ )

Let  $r[0 \dots n]$  be a new array

**for**  $i = 0$  **to**  $n$

$r[i] = -\infty$

**return** MEMOIZED-CUT-ROD-AUX( $p, n, r$ )

MEMOIZED-CUT-ROD-AUX( $p, n, r$ )

**if**  $r[n] \geq 0$

**return**  $r[n]$

**if**  $n == 0$

$q = 0$

**else**  $q = -\infty$

**for**  $i = 1$  **to**  $n$

$q = \max(q, p[i] + \text{MEMOIZED-CUT-ROD-AUX}(p, n - i, r))$

$r[n] = q$

**return**  $q$

26 / 49

## Running time

- ▶ Each subproblem is only solved once.
- ▶ Subproblems have sizes  $0, 1, \dots, n$ , and require a for loop over its size.
- ▶ Running time is also  $\Theta(n^2)$ .

27 / 49

## Longest Common Subsequence (LCS)

- ▶ Given two sequences,  $X = x_1x_2 \dots x_m$  and  $Y = y_1y_2 \dots y_n$ , find a common subsequence between  $X$  and  $Y$  which is as long as possible.
- ▶ Example:
  - ▶  $X = \text{p a c i f i c}$
  - ▶  $Y = \text{a t l a n t i c}$
  - ▶  $\text{LCS}(X, Y) = \text{a i c}$

28 / 49

## Brute force algorithm

- ▶ Generate all subsequences of  $X$  and for each one check if it is also a subsequence of  $Y$ , keeping aside the longest common subsequence found so far.
- ▶ Running time?
  - ▶  $\Theta(2^m) \rightarrow$  to generate all subsequences of  $X$ .
  - ▶  $\Theta(n) \rightarrow$  to check if a subsequence of  $X$  is a subsequence of  $Y$ .
  - ▶ Total:  $\Theta(n 2^m)$
  - ▶ Exponential. Very bad!

29 / 49

## Can we apply dynamic programming?

- ▶ If yes we should be able to define the problem recursively in terms of subproblems.
- ▶ The number of subproblems has to be relatively small (polynomial in  $n$  and  $m$ ) so that dynamic programming can be useful.
- ▶ Once we define the problem in terms of subproblems, we can solve it bottom-up starting with the base cases and storing the solutions as we move to larger and larger subproblems.

30 / 49

## Optimal substructure

- ▶ Let's look at prefixes of  $X$  and  $Y$ .
- ▶ Let  $X_i$  be the prefix of the the first  $i$  elements of  $X$ .
- ▶ Example:  $X = \text{p a c i f i c}$ 
  - ▶  $X_4 = \text{p a c i}$
  - ▶  $X_0 = \emptyset$
  - ▶  $X_7 = \text{p a c i f i c}$

31 / 49

## Optimal substructure

- ▶ Let  $X = x_1 x_2 \dots x_m$  and  $Y = y_1 y_2 \dots y_n$ .
- ▶ Let  $Z = z_1 z_2 \dots z_k$  be a LCS between  $X$  and  $Y$ .
- ▶ Three cases:
  1. If  $x_m = y_n$ , then  $z_k = x_m = y_n$  and  $Z_{k-1}$  is a LCS between  $X_{m-1}$  and  $Y_{n-1}$ .
  2. If  $x_m \neq y_n$  and  $z_k \neq x_m$ , then  $Z$  is a LCS between  $X_{m-1}$  and  $Y_n$ .
  3. If  $x_m \neq y_n$  and  $z_k \neq y_n$ , then  $Z$  is a LCS between  $X_m$  and  $Y_{n-1}$ .

32 / 49

## Proof of case 1

Case 1: If  $x_m = y_n$ , then  $z_k = x_m = y_n$  and  $Z_{k-1}$  is a LCS between  $X_{m-1}$  and  $Y_{n-1}$ .

- ▶ We need to prove that  $z_k = x_m = y_n$ . Suppose that's not true. Then the subsequence  $Z' = z_1 z_2 \dots z_k x_m$  is a common subsequence between  $X$  and  $Y$  and has length  $k + 1$ .
  - ▶  $\Rightarrow$  Contradicts  $Z$  being a LCS between  $X$  and  $Y$ .

33 / 49

## Proof of case 1

- ▶ We now need to prove that  $Z_{k-1}$  is a LCS between  $X_{m-1}$  and  $Y_{n-1}$ . Suppose there is a subsequence  $W$  common to  $X_{m-1}$  and  $Y_{n-1}$  which is longer than  $Z_{k-1}$ .
  - ▶  $\Rightarrow$  length of  $W \geq k$ .
- ▶ The subsequence  $W' = W \parallel x_m$  is common to  $X$  and  $Y$  and has length  $\geq k + 1$ .
  - ▶ Contradicts  $Z$  being a LCS between  $X$  and  $Y$ .

34 / 49

## Proof of cases 2 and 3

Case 2: If  $x_m \neq y_n$  and  $z_k \neq x_m$ , then  $Z$  is a LCS between  $X_{m-1}$  and  $Y_n$ .

- ▶ Suppose there is a subsequence  $W$  common to  $X_{m-1}$  and  $Y_n$  with length  $> k$ . Then  $W$  is a common subsequence between  $X$  and  $Y$ .
  - ▶  $\Rightarrow$  Contradicts  $Z$  being a LCS between  $X$  and  $Y$ .

Case 3: If  $x_m \neq y_n$  and  $z_k \neq y_n$ , then  $Z$  is a LCS between  $X_m$  and  $Y_{n-1}$ .

- ▶ Proof of case 3 is analogous to case 2.

35 / 49

## In summary

We can define  $\text{LCS}(X_m, Y_n)$  in terms of subproblems.

$$\text{LCS}(X_m, Y_n) = \begin{cases} \emptyset & , \text{ if } m = 0 \text{ or } n = 0 \\ \text{LCS}(X_{m-1}, Y_{n-1}) \parallel x_m & , \text{ if } x_m = y_n \\ \text{LCS}(X_{m-1}, Y_n) \text{ or } \text{LCS}(X_m, Y_{n-1}) & , \text{ or } x_m \neq y_n \end{cases}$$

36 / 49

## Length of LCS( $X, Y$ )

- ▶ Let us try to solve a simpler problem: Obtain  $|\text{LCS}(X, Y)| \rightarrow$  the length of  $\text{LCS}(X, Y)$
- ▶ Let  $c[i, j] = |\text{LCS}(X_i, Y_j)|$
- ▶ We want to obtain  $c[m, n]$

37 / 49

## Recursive definition of $c[i, j]$

$$c[i, j] = \begin{cases} 0 & , \text{ if } i = 0 \text{ or } j = 0 \\ c[i - 1, j - 1] + 1 & , \text{ if } i, j > 0 \text{ and } x_i = y_j \\ \max(c[i - 1, j], c[i, j - 1]) & , \text{ if } i, j > 0 \text{ and } x_i \neq y_j \end{cases}$$

38 / 49

## Recursive algorithm

```
LCS-LENGTH-REC( $X, Y, i, j$ )
  if  $i == 0$  or  $j == 0$ 
    return 0
  elseif  $X[i] == Y[j]$ 
    return LCS-LENGTH-REC( $X, Y, i - 1, j - 1$ ) + 1
  else  $a = \text{LCS-LENGTH-REC}(X, Y, i - 1, j)$ 
        $b = \text{LCS-LENGTH-REC}(X, Y, i, j - 1)$ 
       return  $\max(a, b)$ 
```

- ▶ Initial call:  $\text{LCS-LENGTH-REC}(X, Y, m, n)$
- ▶ Similarly to  $\text{FIB-REC}$ , the tree gives rise to many repeated subproblems.
- ▶ The algorithm's running time is exponential. But the number of distinct subproblems is  $= m \cdot n$ .

39 / 49

## We can dynamic programming

```
LCS-LENGTH-DP( $X, Y$ )
   $m = X.length$ 
   $n = Y.length$ 
  for  $i = 1$  to  $m$ 
     $c[i, 0] = 0$ 
  for  $j = 0$  to  $n$ 
     $c[0, j] = 0$ 
  for  $i = 1$  to  $m$ 
    for  $j = 1$  to  $n$ 
      if  $X[i] == Y[j]$ 
         $c[i, j] = c[i - 1, j - 1] + 1$ 
      elseif  $c[i - 1, j] \geq c[i, j - 1]$ 
         $c[i, j] = c[i - 1, j]$ 
      else  $c[i, j] = c[i, j - 1]$ 
  return  $c[m, n]$ 
```

40 / 49

## Example

|     | ∅ | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|-----|---|---|---|---|---|---|---|---|---|
|     |   | a | t | l | a | n | t | i | c |
| ∅   | ∅ | ∅ | ∅ | ∅ | ∅ | ∅ | ∅ | ∅ | ∅ |
| 1 p | ∅ | ∅ | ∅ | ∅ | ∅ | ∅ | ∅ | ∅ | ∅ |
| 2 a | ∅ | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| 3 c | ∅ | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 2 |
| 4 i | ∅ | 1 | 1 | 1 | 1 | 1 | 1 | 2 | 2 |
| 5 f | ∅ | 1 | 1 | 1 | 1 | 1 | 1 | 2 | 2 |
| 6 i | ∅ | 1 | 1 | 1 | 1 | 1 | 1 | 2 | 2 |
| 7 c | ∅ | 1 | 1 | 1 | 1 | 1 | 1 | 2 | 3 |

- $c[i, j]$  is filled row by row, from left to right.

41 / 49

## How to obtain the LCS itself?

- Our algorithm only gets the length of the LCS.
- The idea is to change the code of LCS-LENGTH-DP so that each time we obtain a given  $c[i, j]$ , we record how it was obtained.
- This allows us to reconstruct the solution.

42 / 49

## Modified pseudocode

LCS-LENGTH-DP-v2( $X, Y$ )

```

∴
for i = 1 to m
  for j = 1 to n
    if  $X[i] == Y[j]$ 
       $c[i, j] = c[i - 1, j - 1] + 1$ 
       $b[i, j] = "↖"$ 
    elseif  $c[i - 1, j] \geq c[i, j - 1]$ 
       $c[i, j] = c[i - 1, j]$ 
       $b[i, j] = "↑"$ 
    else  $c[i, j] = c[i, j - 1]$ 
       $b[i, j] = "←"$ 
  return  $c[m, n]$ ,  $b$ 

```

43 / 49

## Example

|     | ∅ | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|-----|---|---|---|---|---|---|---|---|---|
|     |   | a | t | l | a | n | t | i | c |
| ∅   | ∅ | ∅ | ∅ | ∅ | ∅ | ∅ | ∅ | ∅ | ∅ |
| 1 p | ∅ | ↑ | ↑ | ↑ | ↑ | ↑ | ↑ | ↑ | ↑ |
| 2 a | ∅ | ← | ← | ↖ | ← | ← | ← | ← | ← |
| 3 c | ∅ | ↑ | ↑ | ↑ | ↑ | ↑ | ↑ | ↑ | ↖ |
| 4 i | ∅ | ↑ | ↑ | ↑ | ↑ | ↑ | ↑ | ↖ | ↑ |
| 5 f | ∅ | ↑ | ↑ | ↑ | ↑ | ↑ | ↑ | ↑ | ↑ |
| 6 i | ∅ | ↑ | ↑ | ↑ | ↑ | ↑ | ↖ | ↖ | ↑ |
| 7 c | ∅ | ↑ | ↑ | ↑ | ↑ | ↑ | ↑ | ↖ | ↖ |

- The arrows  $↑$ ,  $←$ , and  $↖$  are stored in  $b[i, j]$ .
- $b[i, j]$  indicates the subproblem chosen to obtain  $c[i, j]$ .

44 / 49

- ▶ Having matrix  $b$  filled in, we can easily obtain a LCS between  $X$  and  $Y$ .
- ▶ Initial call:  $\text{PRINT-LCS}(b, X, m, n)$

```

PRINT-LCS( $b, X, i, j$ )
  if  $i == 0$  or  $j == 0$ 
    return // Do nothing
  if  $b[i, j] == "\nwarrow"$ 
    PRINT-LCS( $b, X, i - 1, j - 1$ )
    print  $X[i]$ 
  elseif  $b[i, j] == "\uparrow"$ 
    PRINT-LCS( $b, X, i - 1, j$ )
  else
    PRINT-LCS( $b, X, i, j - 1$ )

```

45 / 49

## Complexity

- ▶ Running time is  $\Theta(m \cdot n)$
- ▶ Again, dynamic programming allowed us to reduce from exponential to polynomial complexity.
- ▶ Your textbook has more examples.

46 / 49

## Memoized version of LCS-LENGTH

```

LCS-LENGTH-MEMOIZED( $X, Y$ )
   $m = X.length$ 
   $n = Y.length$ 
  for  $i = 0$  to  $m$ 
    for  $j = 0$  to  $n$ 
       $c[i, j] = \text{UNKNOWN}$ 
  return M-LCS-LENGTH( $X, Y, m, n$ )

```

47 / 49

```

M-LCS-LENGTH( $X, Y, i, j$ )
  if  $c[i, j] == \text{UNKNOWN}$ 
    if  $i == 0$  or  $j == 0$ 
       $c[i, j] = 0$ 
    elseif  $X[i] == Y[j]$ 
       $c[i, j] = \text{M-LCS-LENGTH}(X, Y, i - 1, j - 1) + 1$ 
    else
       $a = \text{M-LCS-LENGTH}(X, Y, i - 1, j)$ 
       $b = \text{M-LCS-LENGTH}(X, Y, i, j - 1)$ 
       $c[i, j] = \max(a, b)$ 
  return  $c[i, j]$ 

```

48 / 49

## How to apply dynamic programming?

To apply *dynamic programming* or *memoization* to solve a problem we need to do 4 things:

1. Characterize the structure of an optimal solution.
2. Define the value of an optimal solution recursively in terms of optimal solutions of subproblems.
3. Compute the value of the optimal solution bottom-up (in case of dynamic programming) or top-down (in case of memoization).
4. Obtain the optimal solution from the information previously computed and stored in step 3.
